Atmospheric Intelligence Report • 2/20/2026

AQI Classification: Moderate

Dominant pollutant driving air quality is CO (670.0 µg/m³).

Forecast Model

Executive Summary

Current air quality in Delhi is classified as Moderate, with an AQI of 164.76. This level indicates that sensitive individuals may experience respiratory symptoms and minor discomfort, while healthy individuals are unlikely to be significantly affected. Vigilance is advised for those with pre-existing conditions.

PM10 Analysis

Current Concentration: 93.23 $\mu\text{g}/\text{m}^3$

The PM10 concentration is moderately high at 93.23 $\mu\text{g}/\text{m}^3$, exceeding recommended limits for good air quality. While larger particles, this level can still lead to respiratory irritation and exacerbate existing conditions in sensitive individuals. Sources typically include road dust, construction activities, and natural processes contributing to coarser particulate matter.

NO2 Analysis

Current Concentration: 24.27 $\mu\text{g}/\text{m}^3$

Nitrogen Dioxide levels are relatively low at 24.27 $\mu\text{g}/\text{m}^3$, well within healthy limits. This concentration indicates minimal immediate public health concern from NO2 exposure. Typically, NO2 is associated with vehicular emissions and industrial processes, suggesting these sources are not significantly impacting current ambient air quality in Delhi.

Ozone Analysis

Current Concentration: 32.92 µg/m³

Ground-level Ozone concentration is currently low at 32.92 µg/m³. At this level, it poses negligible health risks to the general population. Ozone is a secondary pollutant formed by reactions of other pollutants in sunlight, so low levels suggest either reduced precursor emissions or less intense solar radiation conditions during the measurement period.

Secondary Indicators

Supporting Atmospheric Context

NH₃ (30.12 µg/m³)

Snapshot Interpretation: The current Ammonia concentration stands at 30.12 µg/m³. This real-time value represents the immediate atmospheric presence of NH₃, which can contribute to secondary particulate formation and has a distinct pungent odor. Its primary sources are typically agricultural activities, waste decomposition, and certain industrial processes.

SO₂ (4.42 µg/m³)

Sulphur Dioxide levels are very low at 4.42 µg/m³, indicating minimal contribution from industrial combustion or power generation. At this concentration, SO₂ poses no significant health risk to the general public and is well below any regulatory thresholds for concern. Its presence is negligible in the current air quality profile.

CO (670.00 µg/m³)

Snapshot Interpretation: The current Carbon Monoxide concentration is 670 µg/m³. This real-time reading reflects the immediate presence of CO in the atmosphere. CO is typically emitted from incomplete combustion processes, such as vehicle exhaust, industrial activities, and residential heating, and can impair oxygen transport in the bloodstream.
